

RISK PREMIUM INVEST

Daily analysis of the US Treasuries Market

16 December 2022

	Fed Funds	3-month (Tbills)	1-year	2-year	5-year	10-year
Rates	4.23	4.39	4.62	4.18	3.62	3.48
Daily changes (bp)	0	0	-4	-6	-1	3

Source: Federal Reserve, H15. (with small tweaks to smooth out the impact of benchmarks changes).

Highlights:

- Rates moved in a rather strange way with a significant decline at the short-end of the curve and an increase at the long-end.
- The decline at the short end was clearly related to the release of weak economic indicators, while risk premia increased at the long end in a market still confused by the Fed's recent communication.

PART I : Changes in expected Fed Funds.

PART II : Risk premia contributions.

PART III : Methodological annex.

PART I : CHANGES IN EXPECTED FED FUNDS

The Fed Funds rates expected by investors are estimated by our proprietary model using both various surveys (the monthly “Consensus Economics” survey and the quarterly “Survey of Professional Forecasters”) and the rich information contained in the yield curve (see the methodological annex). The estimates are changed when more recent surveys are available (on December 8, the December “Consensus Forecast” was introduced).

Expectations for future Fed funds rates fell slightly after the release of very weak S&P Global PMIs which pointed to a deep recession. The decline in expected rates was somewhat limited by the hawkish speeches of several senior Fed policy makers on Friday.

	Current	Expected in three months	Expected in six months	Expected in one year	Expected in three years	Expected equilibrium
Fed Funds	4.23	4.61	4.97	4.49	2.54	1.89
Daily changes (bp)	0	0	-1	-3	-2	-1

The fight against inflation is far from over. Investors still expect further significant monetary policy tightening in 2022-2023 (Fed Funds rate at 4.97% in six months and 4.49% in one year, less than in the Fed’s projections). But they believe that the equilibrium long term rate (or “neutral” rate) will be rather low (1.89%). Their confidence is probably based on two key assumptions. On the one hand, the Fed will succeed in its fight against inflation and bring back price increases in the long term around 2% per annum. On the other hand, for structural reasons, the equilibrium “risk-free” real rate is considered rather low. This optimistic view about the real “risk-free” rate may be challenged in the future given the lack of control over fiscal policies in many parts of the world.

Main market-moving news: 16 December 2022

US Macroeconomics

S&P Global Manufacturing PMI Flash for Dec at 46.2 (Expected 47.7; Prior 47.7).

S&P Global Services PMI Flash for Dec at 44.4 (Expected 46.8; Prior 46.2).

S&P Global Composite Flash PMI for Dec at 44.6 (Expected 47.0; Prior 46.4).

Others

New York and San Francisco Fed Presidents John Williams and Mary Daly said that interest rates will remain restrictive for the foreseeable future, climbing higher and staying there longer than markets expected.

PART II : RISK PREMIA ANALYSIS

For US Treasuries, as for all financial assets, there are two key different types of risk premia:

- The short-term **tactical risk premia**: How much excess returns investors require to hold various risky assets at their tactical horizon (which depends on investors, but is often around 3 months)? The tactical positions taken by investors relative to their benchmarks (“neutral”, “short”, “long”) depend on these tactical risk premia.
- The **“buy-and-hold” or “embedded” risk premia**. How much excess return **long-term investors** expect if they hold risky assets over an extended horizon? In the case of US Treasuries, the buy-and-hold risk premia are the differences between the zero-coupon rates of various maturities and the (annualized) expected return on a fund invested in Fed Funds over the same period.

We estimate both types of risk premia (see the methodological annex) but we discuss here only the buy-and-hold risk premia.

The Fed does not make life easier for investors by publishing economic projections and forward guidance deemed to be not very credible! The markets do not know what to fear more: poorly controlled inflation (higher risk premia on US Treasuries) or a deep recession caused by a mistake by the Fed (lower risk premia on US Treasuries). On Friday, long-term rates increased despite the release of very weak economic indicators, and this means that risk premia on long-term Treasuries increased significantly. But the decline in 2-year rates was slightly too pronounced to be fully explained by Fed funds rate expectations, and our model estimates that risk premia on short term Treasuries declined slightly.

	2-year	5-year	10-year
Buy-and-hold risk premia	0.01	0.47	0.93
Daily changes (bp)	-3	2	5

With a long-term perspective, it appears that the buy-and-hold risk premia on long-term Treasuries are very high (see the right-hand side graph). This may not come as a surprise with inflationary risks and generally a strong positive correlation between the price of bonds and equities. Yet, since the beginning of Fed’s Quantitative Easing in 2010, there has been only two episodes where the buy-and-hold risk premia on 10-year US Treasuries have been significantly positive: the 2013 “taper tantrum” and the 2021 “reflation trade” episodes where investors introduced large short positions in Treasuries. Both time, these relatively high short positions and positive risk premia proved unsustainable and risk premia came back later on negative territory.

Looking forward, changing buy-and-hold risk premia should continue to introduce a lot of volatility in the US Treasuries markets. On the one hand, there is still an excess demand for long-term Treasuries and, we believe, a tendency for risk premia to go back on negative territory as soon as inflationary risks recede (and negative betas come back!). On the other hand, the market will have in the future to absorb a larger supply with the Fed starting to cut its holding of bonds (“Quantitative Tightening”). This may push many investors to introduce again large short positions in the belief that long-term rates are now on a structural upward trend.

PART III : METHODOLOGICAL ANNEX

There is an abundant academic literature trying to extract from the yield curve the monetary policy path expected by investors and the risk premia embedded in the observed US Treasuries rates.

One of the best-known statistical models is the model developed by the Federal Reserve Bank of New-York. Their estimates are published daily on the NY Fed website (see www.newyorkfed.org/research/data_indicators/term-premia-tabs#/overview). Strangely enough, these estimates don't seem to be used by many markets practitioners when they discuss the shape of the yield curve and how it can be explained by short-rates expectations and risk premia. One of the reasons is that the results of the model are often quite unrealistic. To illustrate that observation, we can compare the average short rates expected by investors over the next 10 years according to this model with what professional forecasters expect (answers, once a year in February, to the well-regarded survey managed by the Federal Reserve Bank of Philadelphia. See www.philadelphiafed.org/surveys-and-data/real-time-data-research/survey-of-professional-forecasters).

There are many reasons why the average investor's view priced into the market may differ somewhat from the answer given by professional forecasters, but the difference is often much too large to be realistic.

The truth is that the estimates published on the NY Fed website are rather imprecise. There is indeed a large academic literature stressing that the yield curve alone does not contain enough information to extract the investors' underlying views and that the results of surveys should be incorporated in the extraction process (see Kim, Don H., and Athanasios Orphanides, 2012, Term structure estimation with survey data on interest rate forecasts, *Journal of Financial and Quantitative Analysis* 47).

Our model belongs to this class of models that combine information coming from well-regarded surveys with the observed yield curve. But its key originality is elsewhere. Our model does not extract only the buy-and-hold risk premia, but it also extracts the important short-term tactical risk premia required by investors on bonds of various maturities. These tactical risk premia are very important to understand the shape of the yield curve (see the references at the end of this page). One very important result of our work is that until the recent inflationary fears these tactical risk premia have been on average negative since the end 90s (the following graph represents the annualized excess return expected by investors on 10-year Treasuries at the 3-month horizon).

That means that a long time before the Fed introduced QE there was already an insufficient supply of risk-free Treasuries: tactical positions were on average structurally short in this key market. To keep it simple, this rich information about tactical risk premia is not discussed in this daily comment, but an excel file with the full information is available on our website (see the link on the homepage of www.riskpremium.com)
