

RISK PREMIUM INVEST

Daily analysis of the US Treasuries Market 3 May 2023

	Fed Funds	3-month (Tbills)	1-year	2-year	5-year	10-year
Rates	4.83	5.17	4.63	3.92	3.37	3.38
Daily changes (bp)	0	4	-3	-9	-9	-5

Source: Federal Reserve, H15. (with small tweaks to smooth out the impact of benchmarks changes).

Highlights:

- US Treasuries yields fell slightly on Wednesday.
- The FOMC statement was broadly as expected, but Chairman Powell sounded slightly less hawkish than expected at the following press conference.

PART I : Changes in expected Fed Funds.

PART II : Risk premia contributions.

PART III : Methodological annex.

PART I : CHANGES IN EXPECTED FED FUNDS

Fed funds futures provide a biased estimate of investors' true expectations, as they are influenced by varying risk premia. The Fed Funds rates expected by investors are here estimated by our proprietary model using both different surveys (the monthly "Consensus Economics" survey and the quarterly "Survey of Professional Forecasters") and the rich information contained in the yield curve (see the methodological annex). Estimates are revised when more recent surveys become available (on April 18, the April "Consensus Forecast" was introduced).

The FOMC statement and Chairman Powell's subsequent press conference did not bring any significant surprises. The Fed raised rates by 25 basis points as expected and made clear that it believed there was a good chance that monetary policy is now tight enough to drive inflation gradually to its 2% target. As Powell put it, "If you add up all the tightening that's going on through various channels, we feel like we're getting close or are maybe even there" on monetary policy. At the same time, they insist that inflation is still too high, and Powell continued to argue that a rate cut this year is unlikely. But he was maybe not as firm as expected as he hinted that this hawkish stance was not as firmly entrenched and was also dependent on data: "in that world, if that forecast (about inflation) is broadly right". As a result, investors increased their bet that rates will fall as early as the second half of this year, with even a (very slim) chance of a rate cut as early as July.

	Current	Expected in three months	Expected in six months	Expected in one year	Expected in three years	Expected equilibrium
Fed Funds	4.83	4.94	4.90	3.94	2.59	2.55
Daily changes (bp)	0	3	-1	-9	-9	-3

Expectations for future Fed funds diverged even more from the central scenario put forward by the Fed at the end of the March FOMC meeting. While stressing the large uncertainties it faces, the Fed expected rates to be at 5.1% at the end of 2023 and still at 4.3% at the end of 2024, and nothing in the May statement shows that they have changed their mind. But, according to our estimates, investors expect fed funds rates to fall to 3.94% a year from now (due to negative risk premia on short term US Treasuries - see our estimates next page - Fed funds futures at this horizon are even lower, the May 2024 Fed funds forward rate was 3.59% on Wednesday evening).

Main market-moving news: 3 May 2023

US Macroeconomics

ISM Non-Manufacturing PMI for Apr at 51.9 (Expected 51.8; Prior 51.2).

ADP National Employment for Apr at 296,000 (Expected 148,000; Prior 145,000 revised at 142,000)

Others

As expected the Fed raised its target by 25 bp to the 5-5.25% range.

PART II : RISK PREMIA ANALYSIS

For US Treasuries, as for all financial assets, there are two key different types of risk premia:

- The short-term **tactical risk premia**: How much excess returns investors require to hold various risky assets at their tactical horizon (which depends on investors, but is often around 3 months)? The tactical positions taken by investors relative to their benchmarks (“neutral”, “short”, “long”) depend on these tactical risk premia.
- The **“buy-and-hold” or “embedded” risk premia**. How much excess return **long-term investors** expect if they hold risky assets over an extended horizon? In the case of US Treasuries, the buy-and-hold risk premia are the differences between the zero-coupon rates of various maturities and the (annualized) expected return on a fund invested in Fed Funds over the same period.

We estimate both types of risk premia (see the methodological annex and our excel file) but we discuss here only the buy-and-hold risk premia.

Risk premia on US Treasuries were broadly stable on Wednesday with, according to our estimates, a slight decline for 2-year bonds, as Chairman Powell appeared slightly less hawkish than expected.

	2-year	5-year	10-year
Buy-and-hold risk premia	-0.15	0.20	0.54
Daily changes (bp)	-3	-2	1

With a long-term perspective, it appears that the buy-and-hold risk premia on long-term Treasuries are still quite high (see the right-hand side graph). This may not come as a surprise with some inflationary risks remaining and often – but not always - a positive correlation between the price of long-term bonds and equities. Yet, since the beginning of Fed’s Quantitative Easing in 2010, there has been only two episodes where the buy-and-hold risk premia on 10-year US Treasuries have been significantly positive: the 2013 “taper tantrum” and the 2021 “reflation trade” episodes where investors introduced large short positions in Treasuries. Both time, these relatively high short positions and positive risk premia proved unsustainable and risk premia came back later on negative territory.

Looking forward, changing buy-and-hold risk premia should introduce a lot of volatility in the US Treasuries markets. On the one hand, there is still an excess demand for long-term Treasuries and, we believe, a tendency for risk premia to go back on negative territory –this is already the case for 2-year bonds - as soon as inflationary risks recede (and negative betas come back!). On the other hand, the market will have in the future to absorb a larger supply with the Fed starting to cut its holding of bonds (“Quantitative Tightening”). This may push many investors to introduce again large short positions in the belief that long-term rates are now on a structural upward trend.

PART III : METHODOLOGICAL ANNEX

There is an abundant academic literature trying to extract from the yield curve the monetary policy path expected by investors and the risk premia embedded in the observed US Treasuries rates.

One of the best-known statistical models is the model developed by the Federal Reserve Bank of New-York. Their estimates are published daily on the NY Fed website (see www.newyorkfed.org/research/data_indicators/term-premia-tabs#/overview). Strangely enough, these estimates don't seem to be used by many markets practitioners when they discuss the shape of the yield curve and how it can be explained by short-rates expectations and risk premia. One of the reasons is that the results of the model are often quite unrealistic. To illustrate that observation, we can compare the average short rates expected by investors over the next 10 years according to this model with what professional forecasters expect (answers, once a year in February, to the well-regarded survey managed by the Federal Reserve Bank of Philadelphia. See www.philadelphiafed.org/surveys-and-data/real-time-data-research/survey-of-professional-forecasters).

There are many reasons why the average investor's view priced into the market may differ somewhat from the answer given by professional forecasters, but the difference is often much too large to be realistic.

The truth is that the estimates published on the NY Fed website are rather imprecise. There is indeed a large academic literature stressing that the yield curve alone does not contain enough information to extract the investors' underlying views and that the results of surveys should be incorporated in the extraction process (see Kim, Don H., and Athanasios Orphanides, 2012, Term structure estimation with survey data on interest rate forecasts, *Journal of Financial and Quantitative Analysis* 47).

Our model belongs to this class of models that combine information coming from well-regarded surveys with the observed yield curve. But its key originality is elsewhere. Our model does not extract only the buy-and-hold risk premia, but it also extracts the important short-term tactical risk premia required by investors on bonds of various maturities. These tactical risk premia are very important to understand the shape of the yield curve (see the references at the end of this page). One very important result of our work is that until the recent inflationary fears these tactical risk premia have been on average negative since the end 90s (the following graph represents the annualized excess return expected by investors on 10-year Treasuries at the 3-month horizon).

That means that a long time before the Fed introduced QE there was already an insufficient supply of risk-free Treasuries: tactical positions were on average structurally short in this key market. To keep it simple, this rich information about tactical risk premia is not discussed in this daily comment, but an excel file with the full information is available on our website (see the link on the homepage of www.riskpremium.com)

To know more about our modelling of the yield curve, and the key insights it provides on how markets price risks:
