

RISK PREMIUM INVEST

Daily analysis of the US Treasuries Market

18 October 2023

	Fed Funds	3-month (Tbills)	1-year	2-year	5-year	10-year
Rates	5.33	5.60	5.46	5.21	4.92	4.90
Daily changes (bp)	0	-1	0	0	6	7

Source: Federal Reserve, H15. (with small tweaks to smooth out the impact of benchmarks changes).

Highlights:

- Yields on long-term US Treasuries rose again on Wednesday.
- Risk premia rose as concerns about government debt issuance continued to mount.

PART I : Changes in expected Fed Funds.

PART II : Risk premia contributions.

PART III : Methodological annex.

PART I : CHANGES IN EXPECTED FED FUNDS

Fed funds futures provide a biased estimate of investors' true expectations, as they are influenced by varying risk premia. The Fed Funds rates expected by investors are here estimated by our proprietary model using both different surveys (the monthly "Consensus Economics" survey and the quarterly "Survey of Professional Forecasters") and the rich information contained in the yield curve (see the methodological annex). Estimates are revised when more recent surveys become available (on October 13, the October "Consensus Forecast" was introduced).

According to our estimates, expectations for future Fed funds rates at medium term horizons rose a few basis points on Wednesday. There was no obvious trigger. Fed officials were maybe slightly more hawkish than expected with Federal Reserve Bank of New York President John Williams saying that interest rates will need to stay high for a while to get inflation back to the central bank's 2% target (but this is no more a surprising speech...).

	Current	Expected in three months	Expected in six months	Expected in one year	Expected in three years	Expected equilibrium
Fed Funds	5.33	5.45	5.46	4.88	3.56	2.99
Daily changes (bp)	0	-1	2	3	3	1

Even if a majority of FOMC members expect another rate hike before the end of the year, risks seem asymmetric with a significant probability of no hike if core inflation continues to improve despite higher energy prices. As a result, the probability given by investors to a final rate hike is around 50%. According to our estimates, investors have also in mind a different profile for future rate cuts. They still forecast slightly larger rate cuts in 2024 than expected by the "median" FOMC member, but the gap is not very large. More importantly, at longer horizons, they expect Fed funds rates to plateau at a higher level. Investors facing a very resilient economy have gradually become more pessimistic and have raised their average estimates for the long-term neutral rate from 2% at the start of 2022 to around 3% currently (against 2.5% in the Fed's dot plots).

Main market-moving news: 18 October 2023

US Macroeconomics

Housing starts number for Sept at 1.358 mln (Expected 1.380 mln; Prior 1.283 mln revised at 1.269 mln).

Building permits number for Sept at 1.473 mln (Expected 1.450 mln; Prior 1.541 mln revised at 1.543 mln).

Others

China GDP in the third quarter grew more than expected (+4.9% YoY against +4.4% expected).

New York Fed President John Williams said Wednesday interest rates will need to stay high for a while to get inflation back to the central bank's 2% target.

PART II : RISK PREMIA ANALYSIS

For US Treasuries, as for all financial assets, there are two key different types of risk premia:

- The short-term **tactical risk premia**: How much excess returns investors require to hold various risky assets at their tactical horizon (which depends on investors, but is often around 3 months)? The tactical positions taken by investors relative to their benchmarks (“neutral”, “short”, “long”) depend on these tactical risk premia.
- The **“buy-and-hold” or “embedded” risk premia**. How much excess return **long-term investors** expect if they hold risky assets over an extended horizon? In the case of US Treasuries, the buy-and-hold risk premia are the differences between the zero-coupon rates of various maturities and the (annualized) expected return on a fund invested in Fed Funds over the same period.

We estimate both types of risk premia (see the methodological annex and our excel file) but we discuss here only the buy-and-hold risk premia.

Risk premia on US Treasuries rose again on Wednesday. There was no clear trigger, but concerns about government debt issuance seemed to continue to mount. The prospect of “higher for longer” Fed funds rates also makes people reluctant to buy long-term bonds, and the trend toward higher risk premia was only temporarily halted by the war in the Middle East.

	2-year	5-year	10-year
Buy-and-hold risk premia	0.19	0.79	1.32
Daily changes (bp)	-1	3	6

With a long-term perspective, it appears that the buy-and-hold risk premia on long-term Treasuries are very high (see the right-hand side graph). This is also true for the short-term tactical risk premia that we don't discuss here, but play an important role in our analysis of the market (see the annex and the data in the excel file).

This may not come as a surprise with some inflationary risks remaining, a rising public debt and often – but not always - a positive correlation between the price of long-term bonds and equities. Additionally, very high short-term rates may encourage investors to buy short durations bonds rather than long-term bonds. Yet, since the start of Fed's Quantitative Easing in 2010 and until 2022, there have been few episodes where the buy-and-hold risk premia on 10-year US Treasuries were significantly positive. Generally, positive risk premia proved unsustainable and risk premia came back later on negative territory.

Looking forward, changing buy-and-hold risk premia could continue to introduce a lot of volatility in the US Treasuries market. On the one hand, the lessons of the last 10 years on US Treasuries as “safe haven” securities should not be forgotten. There may be a tendency for risk premia to go back on negative territory when inflationary risks recede (with at some stage lower short-term rates and the return of negative betas). On the other hand, the market will have in the future to absorb a larger supply with a large deficit to finance and the Fed cutting its holding of bonds. This may push many investors to introduce again large short positions in the belief that long-term rates are now on a structural upward trend.

PART III : METHODOLOGICAL ANNEX

There is an abundant academic literature trying to extract from the yield curve the monetary policy path expected by investors and the risk premia embedded in the observed US Treasuries rates.

One of the best-known statistical models is the model developed by the Federal Reserve Bank of New-York. Their estimates are published daily on the NY Fed website (see www.newyorkfed.org/research/data_indicators/term-premia-tabs#/overview) and often discussed in newspapers. However, strangely enough, these estimates don't seem to be used by many markets practitioners when they discuss the shape of the yield curve and how it can be explained by short-rates expectations and risk premia. One of the reasons is that the results of the model are often quite unrealistic. To illustrate that observation, we can compare the average short rates expected by investors over the next 10 years according to this model with what professional forecasters expect (answers, once a year in February, to the well-regarded survey managed by the Federal Reserve Bank of Philadelphia. See www.philadelphiafed.org/surveys-and-data/real-time-data-research/survey-of-professional-forecasters).

There are many reasons why the average investor's view priced into the market may differ somewhat from the answer given by professional forecasters, but the difference is often much too large to be realistic.

The truth is that the estimates published on the NY Fed website are rather imprecise. There is indeed a large academic literature stressing that the yield curve alone does not contain enough information to extract the investors' underlying views and that the results of surveys should be incorporated in the extraction process (see Kim, Don H., and Athanasios Orphanides, 2012, Term structure estimation with survey data on interest rate forecasts, Journal of Financial and Quantitative Analysis 47).

Our model belongs to this class of models that combine information coming from well-regarded surveys with the observed yield curve. But its key originality is elsewhere. Our model does not extract only the buy-and-hold risk premia, but it also extracts the important short-term tactical risk premia – current and expected in the future - required by investors on bonds of various maturities. These tactical risk premia are very important to understand the shape of the yield curve (see the references at the end of this page). One very important result of our work is that until the recent inflationary fears and the sharp increase in short-term rates these tactical risk premia have been on average negative since the end 90s (the graph on the left represents the annualized excess return expected by investors on 10-year Treasuries over the 3-month horizon).

That means that a long time before the Fed introduced QE there was already an insufficient supply of risk-free Treasuries: tactical positions were on average structurally short in this key market. These tactical risk premia have increased massively since fall 2022, and their future is very uncertain. To keep it simple, this rich information about tactical risk premia – current and expected in the future - is not discussed in this daily comment, but an excel file with the full information is available on our website.
